Abstract

The study highlights the production of chitinase from *Bacillus cereus* BSH-4, which was isolated from a marine soil source and identified by 16S rRNA gene sequencing. After 96 hours of incubation in shake flask conditions profiling studies showed maximum enzyme activity and growth. The ammonium sulfate precipitation method was used at 80% saturation for partial enzyme purification with further purification done by dialysis wherein the purification fold increased to 1.75. The sodium dodecyl sulfate gel electrophoresis (SDS-PAGE) and silver staining methods were employed to assess the enzyme molecular weight observed to be 60 kDa. The enzyme activity and stability process parameters effects like temperature and pH were studied. At a pH value of 7.0, the greatest enzyme activity was noted which was relatively retained at 80% till pH 9.0. Similarly, higher enzyme activity was observed at a temperature of 30°C and retained 70% relative activity till 60°C, indicating the thermostable nature of the enzyme. Studies on the influence of metal ions showed that Zn²⁺, Cu²⁺, Ca²⁺, Mg²⁺, Mn²⁺, and Fe²⁺ inhibited the enzyme by 20% to 80%. An investigation was also done on the influence of organic solvents like methanol, ethanol, acetone, and isopropyl alcohol on enzyme stability. The results showed that the enzyme was stable in all the solvents, exhibiting 43% to 70% relative activity. The enzyme kinetic studies indicated K_m and V_{max} values of 4.54 mg ml⁻¹ and 76.92 UmL⁻¹ respectively. The enzyme also demonstrated antifungal activity against *Aspergillus niger* NCIM 1207 using the agar well diffusion method.

Keywords: *Bacillus cereus*, Enzyme purification, Chitinase characterization, Enzyme kinetics, Antifungal activity

Introduction

Chitin, a supportive, protective, insoluble polysaccharide (β -1,4-N-acetyl-D-glucosamine) profusely present as a structural constituent in mollusk shells, exoskeleton of arthropods, and fungal cell walls. As a biopolymer, it comes in second globally after cellulose producing more than 10¹⁰ metric tons per year

primarily derived from marine waters alone (Hao *et al.*, 2012; Loni *et al.*, 2014). It is essential to recycle chitin into nature, and this can be achieved by a group of enzymes, namely, lysosomes and chitinases (Korany *et al.*, 2019). Chitinases (EC 3.2.1.14) are the enzymes that hydrolyze homopolymer links of β -1,4-N-acetyl-D-glucosamine into monomer N-acetyl glucosamine (GlcNAc) (Loni *et al.*, 2014). Nutrient uptake, structural changes, defense, and attack are some of the biological functions in which these broadly distributed enzymes take a vital part (Loni *et al.*, 2014). Chitinases are produced by bacteria, fungi, actinomycetes, higher plants, lower animals, and birds (Ghorbel-Bellaaj *et al.*, 2012; Lestari *et al.*, 2017; Cheba *et al.*, 2018). Carbon and nitrogen are sourced from chitin by microorganisms (Lestari *et al.*, 2017; Aktuganov *et al.*, 2018). Microorganisms produce chitinase because they use chitin as an energy source, while fungi and insects produce chitinase because they are involved in morphogenesis (Korany *et al.*, 2019). Among prokaryotes, actinomycetes are the major group producing potent chitinases (Ghorbel-Bellaaj *et al.*, 2012). The main genus of this group is *Streptomyces*; some chitinases are produced by several species such as *S. aureofaciens*, and *S. olivaceoviridis* for resourceful degradation of chitin. Other actinomycetes that produce chitinase include Actinoplanes, Micromonospora, and Nocardia (Aktuganov *et al.*, 2018; Cheba *et al.*, 2018; Ray *et al.*, 2019; Akeed *et al.*, 2020).

The classification of the Chitinase family is done as per the action mechanism i.e., individual hydrolysis mode of the enzyme and homology of their amino acid sequences. Generally, chitinases are randomly splitting hydrolases that recognize the O-glycosyl bond between Chito-saccharide residues for catalysis. There are two classes of chitinase enzymes, namely, endo-chitinases and exo-chitinases (Ray *et al.*, 2019). The hydrolysis of internal O-glycosyl bonds to cleaving the polymers of chitin into oligosaccharides is done by the endo-chitinases, whereas the cleaving of only terminal GlcNAc residues is performed by the exo-chitinases from the chitin polymers' reducing end. The decomposition of chitin polymers into soluble N-acetylglucosamine units is possible due to the dual action of the exo- and endo-chitinases (Ray *et al.*, 2019). There are many reports on the production of chitinases with diverse molecular masses by various bacterial genera, including *Bacillus* (Lestari *et al.*, 2017). Several species of *Bacillus* such as *B. pumilus*, *B. circulans*, *B. subtilis*, *Virgibacillus marismortui*, *B. licheniformis*, *B. cereus*, *Bacillus subtilis*, *B. thuringiensis*, etc. are known to produce chitinase enzyme (Loni *et al.*, 2014; Akeed *et al.*, 2020).

Chitinases find various industrial and environmental applications. They are vital in the geochemical recycling of carbon and nitrogen and give them potential in pest control, bioremediation, and various other biotechnological applications (Loni *et al.*, 2014). The enzyme was used to produce protoplasm when applied to fungal and yeast cells by degrading their cell walls indicating their potential application in the biological control of plant pathogens (Loni *et al.*, 2014; Ray *et al.*, 2019). Chitinases can also be used in the management of marine waste (Hao *et al.*, 2012) and in the production of bioactive derivatives like chitooligosaccharides and functional foods (Le & Yang, 2019).

Chitosan and other derivatives of the enzymes are also increasingly being used in several industries, and enzymatic methods of obtaining them are becoming increasingly important. Traditionally, the chitin was degraded by various chemical and physical methods, which resulted in their low efficiency, high cost, and lack of specificity even though they have been industrialized (Meriem & Mahmoud, 2017). These limitations can be overcome by an eco-friendly enzymatic degradation. As the degradation kinetics of chitinases is relatively slower, the industrial applications of chitinases are limited (Meriem & Mahmoud, 2017). Hence, more efforts and studies are needed to explore newer enzyme sources, adopt better production strategies, and the invention of newer chitinase forms with a wider range of functionality.

In this study *Bacillus cereus*, BSH-04 was used to produce chitinase. Ammonium sulfate precipitation and dialysis were carried out for the partial purification of the enzyme, whereas the molecular weight of the enzyme was determined by SDS-PAGE and silver staining method. The effect of various parameters such as pH, temperature, metal ions, various solvents, and various concentrations of a substrate on chitinase activity was investigated. The antifungal activity of the enzyme was performed using the agar well diffusion method against *Aspergillus niger* NCIM 1207.

Materials and Methods

Isolation and Screening of Chitinolytic Bacteria

The bacterial strain of *Bacillus cereus* BSH-04 was isolated from a marine soil source. The strain was isolated using basal media containing KH_2PO_4 (0.1%), Na_2HPO_4 (0.2%), $\text{CaCl}_2 \cdot 7\text{H}_2\text{O}$ (0.05%), $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ (0.05%), yeast extract (0.25%), NH_4Cl 0.1%, NaCl 0.05%, colloidal chitin (1%), incubated for 96 hrs at 30°C (Shaikh *et al.*, 2018). The chitinolytic activity of the strain was checked by screening the isolate on an agar plate containing 0.5% colloidal chitin as substrate at room temperature with an incubation time of 48 h to 72 hrs.

Molecular Identification of the Bacterial Isolate by 16s Rrna Gene Sequencing

The whole genomic DNA was extracted from the pure culture using the ionic detergent cetyl trimethyl ammonium bromide (CTAB) method. Amplification of 16S fragment (~1300-1500bp) was performed by High-fidelity polymerase using a thermocycler. The amplified fragment was then purified and subjected to

nucleotide sequencing. The fragment was sequenced by primers, 63F (5'CAGGCCTAACACATGCAAGTC3') and 1387R (5'GGCGGATGTGTACAAGGC3'). The sequencing was carried-out using big dye terminator version 3.1 analyzed by ABI 3130 Genetic Analyser. Using the MEGA 6.0 tool, a phylogenetic tree was constructed by the neighbor-joining method.

Colloidal Chitin Preparation

Colloidal chitin used as a substrate for chitinase assay was prepared by dissolving 10 g of chitin flakes in 60 mL of concentrated HCl under constant stirring for 1 to 2 hrs at room temperature. The solution was then poured into 400 mL of deionized water with continuous stirring to form a precipitate. Further centrifugation was employed to collect it and attained the neutral pH after several washes by water thus, obtained colloidal chitin was stored at 4°C until further use (Jha *et al.*, 2016; Bouacem *et al.*, 2018).

Assay of Chitinase Activity

Protein was estimated according to the Lowry method using bovine serum albumin as a standard (Shehata *et al.*, 2018). A spectrophotometer was utilized in the measurement of the chitinolytic activity through the determination of the free groups formed by chitin hydrolysis. The reaction mixture consisted of sodium phosphate buffer (0.2M, pH 7.0) that was used to suspend 1 ml of colloidal chitin (0.5%). The whole content was incubated for 30 min at 37°C, and the reaction was terminated by the addition of 1 mL DNS. Further, the content was heated in boiling water for 5 min and the absorbance of the supernatant was measured at 540 nm. One unit of chitinase activity was defined as the production of 1 μmol (NAG) per minute using a standard curve (N-acetyl glucosamine) (Bouacem *et al.*, 2018).

Profiling Study for Growth and Chitinase Production

Bacterial growth and chitinase production were studied by inoculating the culture at log-phase into a production medium containing colloidal chitin (pH 7). Further, it was incubated at 30°C under constant shaking at 120 rpm. Samples were collected every 24 h for five days. The absorbance at 600 nm from a UV-Visible spectrophotometer was used to measure the culture growth. The growth curve was plotted by considering the incubation time on the X-axis and absorbance on the Y-axis. Each sample was analyzed for enzyme activity by the method explained above (Bouacem *et al.*, 2018).

Partial Purification of Chitinase

The enzyme present in the cell-free supernatant was partially purified by ammonium sulfate precipitation at different saturation concentrations like 70%, 75%, 80%, and 85% at 4°C under constant stirring. The precipitated solution was subjected to centrifugation at 8000 rpm for 20 min at 4°C. The precipitate was again dissolved in 4 ml of sodium acetate buffer (pH 7.0). Consecutively, the crude protein was further subjected to dialysis against the same buffer for 6h at 4°C and the buffer was changed every 3 hrs. The protein content and chitinase activity in each fraction were determined (Kavitha & Vijayalakshmi, 2011).

Molecular Weight Determination by SDS-PAGE

The molecular weight of the partially purified chitinase enzyme was determined by the preference fraction with the highest chitinase activity. Sodium dodecyl sulfate gel electrophoresis (SDS-PAGE) was used to evaluate the molecular weight (Ray *et al.*, 2019), containing 5% and 10% of acrylamide for stacking gel and separating gel, respectively. For protein identification, a sensitive staining method i.e., the silver staining method, was used to detect the molecular weight of partially purified chitinase enzyme (Senol *et al.*, 2014).

Characterization of Partially Purified Chitinase

Effect of pH on Enzyme Activity

The effect of pH on chitinase was identified by incubating the reaction mixture with various pH values from 4 to 10, such as 0.1 M acetate buffer (pH 4–6), 0.1 M phosphate buffer (pH 5–7), and 0.1 M Tris buffer (pH 6.5–10) for 30 min at 37°C. The pH stability for chitinase was determined by incubating the enzyme without substrate in the presence of various pH (4 to 10) for 1h at 4°C, and the relative activity was measured using colloidal chitin as a substrate (Liu *et al.*, 2010; Cheba *et al.*, 2016).

Effect of Temperature on Enzyme Activity

To study the effect of temperature on enzyme activity, we varied the temperature from 10–70°C and performed enzyme assay by standard method. The thermal stability of the enzyme was determined by pre-incubating the enzyme at various temperature ranges (30°C to 80°C) without substrate in the reaction buffer at pH 6.0 for 1 h, later relative activity was calculated by using colloidal chitin as substrate under standard conditions (Liu *et al.*, 2010; Cheba *et al.*, 2016).

Effect of Various Metal Ions on Enzyme Activity

To investigate the effect of different metal ions on enzyme activity metal ions (Zn^{2+} , Cu^{2+} , Ca^{2+} , Mg^{2+} , Mn^{2+} , and Fe^{2+}) were added to the reaction mixture. The final concentration attained was 5 mM and further Chitinolytic activity was tabulated using standard assay protocols.

Effect of Organic Solvents on Enzyme Activity

The study of the influence of various organic solvents on purified chitinase was performed by incubating the enzyme with different solvents, including methanol, ethanol, and acetone, isopropyl alcohol, with a final concentration of 10% and 20%, respectively.

Effect of Substrate Concentration on Enzyme Activity

Colloidal chitin was utilized in the study of substrate affinity. The affinity between substrate and enzyme was determined by incubating the purified chitinase with various colloidal chitin (2 mg mL⁻¹ to 10 mg mL⁻¹). Lineweaver- Burk (LB) curve was used to calculate K_m and V_{max} (Doan *et al.*, 2021).

Antifungal Activity of the Partially Purified Enzyme

The antifungal activity of the partially purified chitinase was tested against *Aspergillus niger* NCIM 1207 using the agar well diffusion method (Delfini *et al.*, 2021). The fungus was seeded (100 µL) onto the potato dextrose agar medium (PDA). Then, 6 mm diameter holes were pressed aseptically, loaded with 100 µL of the partially purified chitinase, and then incubated for four days at 30°C. The antifungal activity was evaluated by measuring (in mm) the inhibition zone of the fungal growth around the hole.

Results and Discussion

Screening of Chitinase Producing Organism

In the current study, a bacterial strain was identified as a chitinase producer based on the formation of clear zones on an agar plate containing 0.5% colloidal chitin and culture at 30°C for 72 hrs. The zone of clearance around the bacterial culture showed extracellular chitinase activity after 72 hrs of incubation in the optimized medium.

Molecular Identification by 16s rRNA Gene Sequencing

Identification of strain was achieved by comparing the 16S rRNA gene sequences of the strain with 16S rRNA gene sequences of the NCBI GenBank database with the help of BLAST; the isolate was found to be *Bacillus cereus* strain BSH-04 (GenBank Accession No. MT672784.1) by analyzing the phylogenetic tree which gave the information related to the highest identity of strain and its evolutionary relationships which was shown in **Figure 1**.

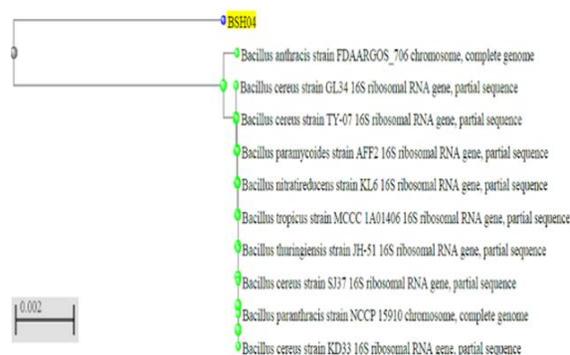

Figure 1. Phylogenetic analysis of *Bacillus cereus* BSH-04

Profiling Study for Growth and Enzyme Production

The bacterial growth and chitinase production were increased from 24 to 96 hrs of incubation and reached a maximum at 96 h. As shown in **Figure 2**, the highest enzyme activity was observed after 96 hrs of incubation later, bacterial growth reached a stationary phase, and enzyme activity decreased.

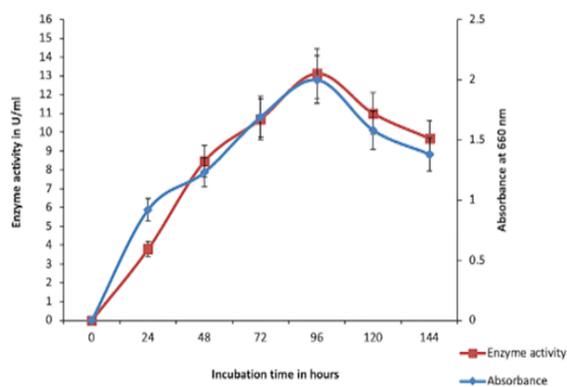

Figure 2. Profiling study for growth and chitinase production by *Bacillus cereus* BSH-04

Purification of Chitinase by Ammonium Sulfate Precipitation and Dialysis

The precipitation of chitinase at diverse ammonium sulphate saturation was performed. The results showed that at 70%, 75%, 80% and 85% saturation enzyme activities reported were 108.67 U/ml, 107.45 U/ml, 143.68 U/ml, and 133.33 U/ml respectively. The highest protein and maximum chitinase activity were observed to be 1.50 mg ml⁻¹ and 143.68 UmL⁻¹, respectively at 80% ammonium sulfate saturation; further dialysis resulted in an increase in the purification fold up to 1.75 along with maximum chitinase activity (288.88 UmL⁻¹) was shown in **Table 1**.

Table 1. Purification table for chitinase enzyme.

Sample name	Total activity (U)	Total protein (mg)	Specific activity (U/mg)	Purification fold
Crude	43763.9	305.95	143.04	1
Dialyzed	1068.56	4.255	251.13	1.75

Molecular Weight Determination by SDS PAGE and Silver Staining

The sodium dodecyl sulfate gel electrophoresis (SDS-PAGE) was employed to assess the enzyme molecular weight which was observed to be 60 kDa. The marker used was 10 kDa to 100 kDa; due to lower loading, sample silver staining was carried out, which is shown in **Figure 3**.

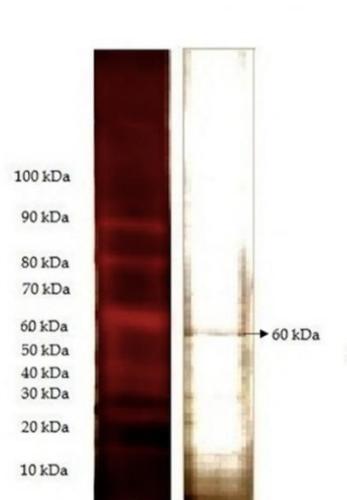

Figure 3. Figure showing molecular weight of partially purified chitinase using SDS-PAGE method

Characterization of Partially Purified Chitinase

Effect of pH on Enzyme Stability and Activity

Figure 4a and **Figure 4b** provide the effect of pH on enzyme stability and activity, respectively. Chitinase activity was less at pH 4.0 and gradually increased from pH 5 to 7 and attained optimum at pH 7.0; further activity decreased from pH 8 to pH 10, which was shown in **Figure 4a**. The stability of chitinase was found in the range of pH 6.0 to 9.0 (**Figure 4b**).

Effect of Temperature on Enzyme Stability and Activity

Enzymes are proteins in nature, inactivates above 50°C, denatures at 70°C, and are unable to provide sufficient activation energy at very lower temperatures (El-Sayed *et al.*, 2019). In this study, the optimum temperature for the purified enzyme was observed at 30°C, which was earlier reported as 37°C by (El-Sayed *et al.*, 2019); after attaining optimum temperature, chitinase activity gradually decreases from 40°C to 70°C (**Figure 4c**). The stability of chitinase was found in the range of 30°C to 60°C (**Figure 4d**).

Effect of Various Metal Ions on Enzyme Activity

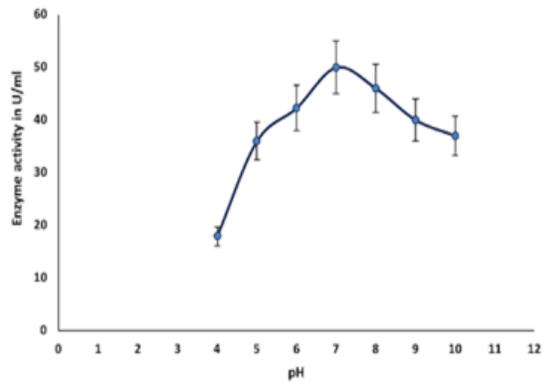

Figure 4e shows the influence on enzyme activity from various metal ions. Inhibition of enzyme at 5mM concentration of all metal ions (Zn²⁺, Mg²⁺, Mn²⁺, Cu²⁺, Ca²⁺, and Fe²⁺) was observed. Zn²⁺ showed lesser inhibition, whereas Fe²⁺ showed the highest enzyme inhibition; overall enzyme inhibition was from 20% to 80%.

Effect of Organic Solvents on Enzyme Activity

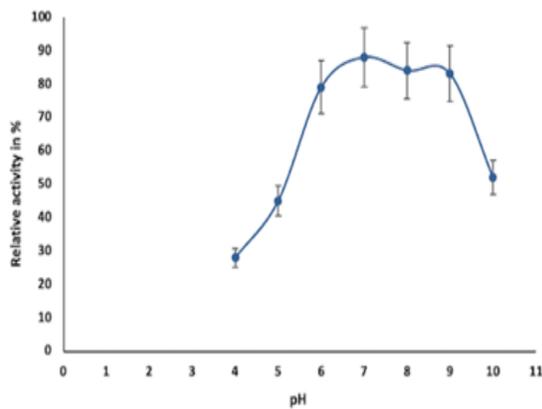

The values for relative enzyme activity with 10% each of ethanol, methanol, acetone and isopropyl alcohol were found to be 47%, 43%, 70%, and 53% respectively. Hence, it is observed that the enzyme is more stable in acetone and less stable in methanol.

Effect of Substrate Concentration

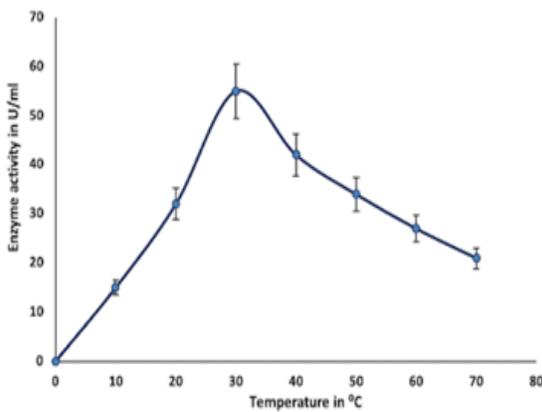

Enzyme activity was found to be optimum at 6 mg ml⁻¹ of colloidal chitin and decreased in the range of 2, 4,8,10 mg ml⁻¹ (colloidal chitin), which is shown in **Figure 4f**.

Determination of K_m and V_{max}

V_{max} and K_m were respectively found to be 76.92 Umg^{-1} and 4.54 mg ml^{-1} , from the Lineweaver-Burk plot shown in **Figure 5** here the small K_m indicates a high affinity of the enzyme towards the colloidal chitin, K_m and V_{max} kinetic constants of purified chitinase from *Paenibacillus spasadensis* CS0611 were reported as 4.41 mg ml^{-1} and 1.08 mg min^{-1} respectively by (Guo *et al.*, 2017);

similarly, K_m and V_{max} of *Bacillus pumilus* JUBCH08 were reported as 0.13 mg ml^{-1} and 38.23 U ml^{-1} respectively by (Bhattacharya *et al.*, 2016).

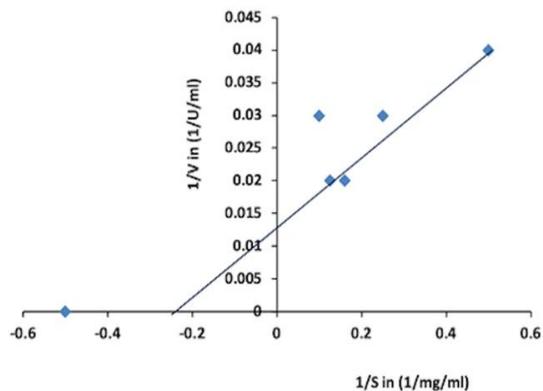

Figure 5. Lineweaver Burk plot (The K_m and V_{max} obtained as 4.54 mg/ml and 76.92 U/mg respectively)

Antifungal Activity

Antifungal activity against *Aspergillus niger* NCIM 1207 was tested by the agar well diffusion method. The zone of inhibition (ZoI) was observed when the partially purified chitinase was added to the PDA agar seeded with fungal spores incubated for 96 h at 30°C . No zone of inhibition was observed in the negative control. In agriculture, the chitinases are used for the biological control of pests and plant fungal pathogens such as *Trichoderma reesei*, *Colletotrichum gleosporoides*, *Phoma medicaginis*, *Rhizoctonia solani*, etc (Oyeleye & Normi, 2018). Similar fungal inhibition was reported against sixteen fungal strains by chitinase enzyme present in the cell-free extract in a previous report (Delfini *et al.*, 2021). The researchers had reported inhibition of hyphae development and germination of spores by cell-free enzyme preparation.

Last few decades, the production of microbial chitinase has attracted attention. Many organisms have been reported to produce chitinase enzyme; the bacteria are the major source of chitinase-producing microorganisms (Bhattacharya *et al.*, 2007). In the present study, the bacterial strain *Bacillus cereus* BSH-04 was isolated from a marine soil source and further used for enzyme production. The profiling study of the bacterial growth and chitinase production from *Bacillus cereus* BSH-04 was studied from 24 hrs to 144 hrs of incubation. From **Figure 2**, a steady-steep growth of bacteria was observed around 0 h to 24 hrs, whereas the production of chitinase was less rapid in the initial growth period of 24 hrs. From the onset of 24 h to 96 hrs, a steady increase in slope was observed (bacterial growth), whereas the enzyme production was also increased. The highest growth and chitinase production was also observed at 96 hrs with maximum chitinase activity of 13.13 UmL^{-1} . Thereafter, declination of the bacterial growth along with chitinase production was observed till 144 hrs. It can be inferred that chitinase is a growth-dependent enzyme, and the production of the enzyme depreciates as the cell undergoes into stationary phase and death phase. In this phase, the chitinolytic activity gradually decreases, which may be due to the

accumulation of by-products resulting in a negative feedback mechanism (Khan *et al.*, 2015).

Partial purification of chitinase enzyme from the supernatant at 80% ammonium sulfate saturation exhibited the highest protein recovery with the highest activity (143.68 UmL^{-1}). Similar results have been reported by earlier researchers (Hammami *et al.*, 2013; Shivakumar *et al.*, 2014). Further purification, i.e., dialysis, has increased the purification fold to 1.75 with a specific activity of 251.13 UmL^{-1} . The sodium dodecyl sulfate gel electrophoresis (SDS-PAGE) and silver staining methods were employed to assess the enzyme molecular weight observed to be 60 kDa. Various bacterial genera (*Bacillus*, *Streptomyces*, *Brevibacillus*, *Serratia*, *Chromobacterium*, etc) were reported to produce chitinase with molecular weights around 60-65 kDa (Poria *et al.*, 2021). Similar reports have been reported by (Bhattacharya *et al.*, 2016; Singh *et al.*, 2021). In a similar study, the molecular weight of chitinase from *Paenibacillus pasadenensis* CS0611 was found to be 69 kDa (Guo *et al.*, 2017). Since the chitinase enzyme is a protein, high temperatures can inactivate or denature the enzyme. This may be due to hydrolysis of the peptide chain, amino acid aggregation, incorrect confirmation, or disruption of amino acids (Shaikh *et al.*, 2018).

Generally, the pH optima for most chitinases were in the acidic range. Hence, changes in the pH value of the medium affect enzyme stability and activity as well. This could be due to the characteristic poly-extremophiles of bacteria present in particular ecosystems (Aktuganov *et al.*, 2018). Metal ions function as links to both the substrate and the enzyme and the substrate, binding to them both thus stimulating enzyme activity by keeping the substrate in the active site of the enzyme (Shivakumar *et al.*, 2014). The effect of metal ions on enzyme activity can also be attributed to the changes in electrostatic bonds that can alter the tertiary structure of the enzyme. This may also be because the sulfhydryl group may be involved in the active site of the enzyme (Shivakumar *et al.*, 2014). **Figure 4e** indicates that the residual activity of chitinase from *Bacillus cereus* BSH-04 was inhibited from 20% to 80% in the presence of metal ions like Zn^{2+} , Cu^{2+} , Ca^{2+} , Mg^{2+} , Mn^{2+} and Fe^{2+} at 5 mM concentration. Fe^{2+} inhibited the chitinase activity to a greater extent, i.e., by almost 80%, and least inhibited by Zn^{2+} , i.e., 20%. Similar results were reported by (Hao *et al.*, 2012; Shivakumar *et al.*, 2014). In contrast, Fe and Mg in (Ghorbel-Bellaaj *et al.*, 2012) and Mg, Ca, and Cu in (Bouacem *et al.*, 2018) have increased the relative chitinase activity. In (Aktuganov *et al.*, 2018), Ca and Mg neither showed any significant inhibitory or activating effects on the enzyme. Enzyme inhibition by Zn may be associated with residues of acids like aspartic and glutamic acids left in chitinase. studies have indicated that these amino acids can bind to specific divalent cations in the active site of chitinase, thereby inhibiting chitinase (Shivakumar *et al.*, 2014).

Our studies showed that the chitinase exhibited a moderate tolerance to some organic solvents such as methanol, ethanol, acetone, and isopropanol. The enzyme activity was inhibited at around 50% in the presence of 10% ethanol, methanol, and isopropyl alcohol. Therefore it can be concluded that the enzyme

stability across the given solvents indicates the suitability of the enzyme in industrial applications.

Lineweaver-Burk plots were used in the determination of the kinetic values of K_m and V_{max} , whose values were found to be 4.54 mg mL⁻¹ and 76.92 Umg⁻¹, respectively (Figure 5). The kinetic parameters K_m and V_{max} define substrate specificity. Lower K_m and higher V_{max} values verify the chitinase enzyme specificity to colloidal chitin (Shehata *et al.*, 2018). Such investigations indicate the suitability of the chitinase enzyme in many biochemical transformations.

Members of the genus *Bacillus* are also known to produce a wide variety of antibacterial compounds, the most biologically active molecules being non-ribosomal and synthetic lipopeptides. *B. amyloliquefaciens* PGP BacCA1 cells showed antifungal effects against some phytopathogenic fungi when applied to bean seeds (Delfini *et al.*, 2021). An important observation from this study is the sprouting inhibition shown for *A. niger* NCIM 1207 by partially purified chitinase, as spore germination is the first step in the activation of the asexual life cycle and the spread of multiple phytopathogenic air fungal diseases. Therefore, if the plant pathogens are inhibited at this stage, this disease can be effectively controlled (Delfini *et al.*, 2021).

Conclusion

Production of chitinase is considered to be an important matter as the recycling of insoluble chitin into its simpler forms. The microbial production of chitinase is considered to be more efficient; therefore, the enzyme production from *Bacillus cereus* BSH-04 was undertaken for the study. The partial purification of 60kDa chitinase resulted in an increase in the purification fold by 1.75. The enzyme demonstrated temperature and pH stability that may be useful in various industrial applications of the enzyme at different temperatures and pH values. The study also depicted various kinetic parameters which are useful to understand the stability of chitinase enzymes under different physicochemical conditions. The antifungal activity as observed against *Aspergillus niger* indicates the use of chitinase both as an antifungal and biocontrol agent.
